                       Ρ
    The Fe-ore powders and similar concs. having reactive
    impurities are pelletized using a low content of polymeric binder, after
    pretreatment with additives for chelating the interfering impurities.
    binder system is typically based on pretreatment of the ore conc. with Na
    citrate to chelate the impurities, followed by wet pelletizing with a
    polymeric binder as an alkali metal salt of CM-cellulose.
     -ore conc. powder is optionally pretreated with Na2CO3 at
    0.005-0.07% and a caustic at 0.005-0.05% for improved bonding with Na
    citrate promoter at 0.005-0.1% and the Na-CMC binder at 0.005-0.2%.
    inactivated impurities are typically S, Mn, Fe(OH)2, Ca2+ ions, and/or
    Mq2+ ions. The hematite ore conc. pelletized at .apprx.8% moisture with
    0.1\ Na citrate and 0.02\ CM-cellulose type binder showed the dry crush
    strength of 25.2 lbs, vs. .apprx.16 lbs with 0.3% bentonite as inorg.
    binder.

    English
    The synthesis of 2 polysaccharide-based graft copolymers with acrylamide,
     i.e., quar gum-grafted polyacrylamide (I) and hydroxypropyl
    guar gum-grafted polyacrylamide (II) is described. The graft
    copolymers were characterized by viscometry, IR spectroscopy, and thermal
    anal. The flocculation characteristics of the graft copolymers were
    studied in kaolin, Fe ore, and silica suspensions.
    For the base polysaccharides, guar gum (III) and hydroxypropyl
    guar gum (IV), it was obsd. that III exhibited better performance
    than IV in all 3 suspensions. For the graft copolymers, II showed better
    performance than I. The flocculation characteristics of the best
    performing graft copolymer II were compared with various com. available
     flocculants in the 3 suspensions mentioned above.

The ore powders and similar materials for pelletizing are premixed with:

(a) 0.01-1% water-sol. polymers as the temporary binder typically based on guar, starch, or cellulose; (b) 0.004-0.15% caustic addn. as hardener, esp. as alkali or alk.-earth hydroxides; and (c) optional small amt. of weak acid selected from soda ash and/or Na citrate. The typical binder system suitable for powd. Fe-ore conc. contains

Na salt of CM-cellulose and NaOH, replacing conventional bentonite as the inorg. binder contributing to increased slag vol. in smelting. The green Fe-ore pellets of .apprx.0.5 in. size with .apprx.10% moisture show the optimized crush strength of .apprx.10 lbs/pellet, vs. only .apprx.5 lbs/pellet without the NaOH hardener. The green pellets are typically heated slowly for drying, and then are fired at .gtoreq.2200.degree. F for hardening.

The water-sol. binders for agglomeration of powd. ores and similar materials contain: (1) the polymer selected from guars, starches, cellulose derivs., and/or similar materials; and (2) the caustic component preferably selected from NaOH, KOH, and/or NH4OH. The binder suitable for powd. Fe ore contains an alkali metal salt of CM-cellulose, and NaOH, optionally with Na2CO3 and/or Na citrate. Thus, powd. Fe-ore conc. contg. 10.1-10.5% moisture was pelletized to .apprx.0.5 in. size using tech. CM-cellulose binder at 0.90 lb/ton ore, and NaOH at 0.12-2.4 lb/ton ore. Dry crush strength of the pellets was increased by the addn. of NaOH to a max. of 7.5 lb at 1.2 lb NaOH/ton ore.

The binder mixt. for use in ore pelletizing consists of: (a) 50-98% powd. or fibrous carrier selected from the minerals contg. Mg and/or Ca, and having high sp. surface area; and (b) 2-50% of a natural polysaccharide as water-sol. binder component having high viscosity. The carrier is preferably selected from fibrous forsterite, or powd. olivine, magnesite, calcite, and dolomite. The polysaccharide is a natural gum, starch, pectin, and/or carrageenan. The ore pellets are manufd. with 0.1-5.0% binder mixt., and show good strength in the green, dried, or fired stage. The binder suitable for Fe-ore concns. having 8.5% moisture contains .apprx.1% synthetic fibrous forsterite as well as guar gum as the polysaccharide.

    The powd. ore is blended with moisture, polymer binders, and a weak acid
AB 
     or its salt for improved pelletizing. The binder polymers are selected from guar. starch, alginates, pectins, polyacrylamides,
    polyacrylates, and poly(ethylene oxides). The weak acid is citric, malic,
     and/or tartaric acid, and is used with the polymer at 0.01-1.0% total
     binder. The binder system for powd. Fe ores is
     preferably guar. and citric acid. The salts are preferably
     those of citric, tartaric, malic fumaric, and/or lactic acids.
     moisture content is typically 7-12% based on solids.

     Powd. moist ore is mixed with powd. binder blend typically contg.
AB
     0.05-0.2% water-sol. natural polymer (esp. guar gum) as well as
     0.005-0.1% synthetic polymer at (2-30):1 ratio and the mixt. is pelletized
     and dried for green strength. The synthetic polymer is preferably based
     on acrylamide with 10-40% Na acrylate. The pelletizing process is
     suitable for Fe ores having particle size <250 .mu.m.
     The typical binder blend for pelletizing at .apprx.10% moisture and 0.12%
     total (based on ore) contains 5 parts of guar gum and 1 part of
     20% anionic polyacrylamide premixed at 1:1 ratio with Na2CO3 for
     conditioning of hard water. The blended binder shows increased green
     strength by comparison with the guar gum.

Powd. ore-conc. mixts. for pelletizing consist of 80-99.98% ore (including AB 6-12% moisture), 0.01-10.0% modified native starch, and an effective amt. of water-dispersible polymer to promote smooth pelletizing. The polymer addn. is selected from natural gums, pectins, starch derivs., cellulose derivs., vinyls, and/or acrylics. The mixt. and process are suitable for pelletizing of Fe ores, and decrease the inorg. impurities assocd. with conventional bentonite binders. The native starch is premixed with preferably 0.5-50% of the polymer and partially gelatinized prior to mixing with the ore conc. in pelletizing. The resulting green pellets have an increased surface smoothness, decreased tackiness, and a slower and more uniform growth compared with the starch-bonded ore pellets. Thus, powd. Fe ore contg. 9.5% moisture was pelletized using 0.118% extruded corn starch and 0.029% nonionic acrylamide binder. The green pellets were hardened by drying at 105.degree., and tumbled on an inclined disk app. for abrasion test. The pellet wear loss was only 0.62%, compared with 1.01% using 0.147% starch

The stability of iron ore reder-water slurries during transport or storage can be improved by milling the slurry with 0.01-1.00 wt.%, preferably 0.05-0.5 wt.%, of a dispersant contg. guar gum or its derivs., and a water-sol. vinyl polymer. The guar gum derivs. are preferably an alkylene oxide adduct or carboxylated compd. of guar gum. Thus, a 74 wt.% iron ore powder-water slurry was ball-milled with 0.15 wt.% of a dispersant contg. 4:1 wt. ratio guar gum/sodium polyacrylate; the mixt. was then stabilized for .gtoreq.24 h and had a viscosity of 1300 cP (at 25.degree.), vs. 2200 cP for a com. dispersant.

Iron ore is transported by pipeline in the form of an aq. slurry contg. 20-45 vol. % of ore, to which is added, by wt.. based on the ore, 0.02-0.4% of an ionic dispersant and 0.01-0.2% based on the water content, of a nonionic organic polymer.

Pref. polymers are polyacrylamide or **guar** gam, with ligno sulphonate as dispersant. The ore may be ground so that 100% is -10 mesh, 95% is -65 mesh, 80% is -200 mesh and 70% is -325 mesh.

The dispersant facilitates transport of increased amts. of very fine ore without development of excessive viscosity, while the polymer prevents drop out of coarse particles. The cost of uniform fine grinding is thereby eliminated.
